

Master Workflow Object (mwf)

Last Modified on 11/30/2017 6:04 am EST

Overview

Use the *mwf* object to retrieve values from a master workflow with a simple expression. With the *mwf* object, you can access master workflow metadata and activity metadata, which you can do from any workflow in a master workflow. All returned values are of the type object, unless you use casting to convert them to an appropriate type. This is necessary in cases such as an IfElse condition.

mwf Object Examples

- *mwf.UpdatedAt*
- *mwf.ActivityScope("Start")*
- *wf.Variables["scmCaseImportance"]=ToBoolean(mwf.Variables["scmCaseImportance"])*- This is a casting example, where *mwf* is used in an IfElse condition that compares a value between the current workflow and the master workflow. Note that *ToBoolean* casting is required for the condition to parse properly.

Use the *mwf* Object in a Form
